Abstract

Given a capacity, the set of dominating k -additive capacities is a convex polytope called the k -additive monotone core; thus, it is defined by its vertices. In this paper we deal with the problem of deriving a procedure to obtain such vertices in the line of the results of Shapley and Ichiishi for the additive case. We propose an algorithm to determine the vertices of the n -additive monotone core and we explore the possible translations for the k -additive case.

Keywords: Polyhedra, capacities, k -additivity, dominance, core.

1 Introduction

One of the main problems of cooperative game theory is to define a solution of a game v , that is, supposing that all players join the grand coalition N , an *efficient pay-off vector* or *pre-imputation* to each player represents a sharing of the total worth of the game $v(N)$. In the case of finite games of n players, a pre-imputation can be written as a n -tuple (x_1, \dots, x_n) such that $\sum_{i=1}^n x_i = v(N)$. Of course, some rationality criterion should prevail when defining the sharing.

In this respect, the core is perhaps the most popular solution of a game. It is defined as the set of pre-imputations x on N such that

$$\sum_{i \in A} x_i \geq v(A), \forall A \subseteq N, A \neq \emptyset \quad \text{and} \quad \sum_{i=1}^n x_i = v(N).$$

It is a well-known fact that the core is nonempty if and only if the game is balanced [1]. For games with an empty core, it is necessary to give an alternative solution. In this sense, many

possibilities have been proposed in the literature, as the dominance core stable sets, Shapley index, Banzhaf index, the ϵ -core, the kernel, the nucleolus, etc. (see e.g. [8]).

On the other hand, Grabisch has defined in [11] the concept of k -additive capacities (capacities are monotone games). These capacities generalize the concept of probability and they fill the gap between probabilities and general capacities. Moreover, as they are defined in terms of the Möbius transform and this transform can be applied to the characteristic function of any game (not necessarily monotone), the concept of k -additivity can be extended to games as well.

In a previous paper [19] we have defined the so-called k -additive core. The basic idea is to remark that an imputation is nothing else than an additive game and, if the core is empty, we may allow to search for games more general than additive ones, namely k -additive games, dominating the game. We have presented a generalization of the concept of balanced games, the k -balanced games; these games are those admitting a dominating k -additive game and no dominating $(k-1)$ -additive game. In that paper it is also defined a generalization of the concept of pre-imputation, the k -imputation; from a k -imputation, we have proposed a procedure to define a classical pre-imputation based on the pessimistic criterion.

In [19] we have seen that for general games, any game is either balanced or 2-balanced. Moreover, while the core is a polytope whose vertices have been obtained by Shapley [25] and Ichiishi [15] for convex games, the 2-additive core is not a polytope but an unbounded convex polyhedron [13].

On the other hand, when dealing with capacities, it makes sense to study the k -additive monotone core, that consists in the set of capacities dominating the capacity; it can be easily seen that the k -additive monotone core is a convex polytope, whence it can be described through its vertices. The aim of this paper is to study these vertices.

Moreover, there are other fields in which it is interesting to find the set of probabilities dominating a capacity. For instance, Dempster [6] and Shafer [24] have proposed a representation of uncertainty based on a “lower probability” or “degree of belief”, respectively, to every event. Their model needs a lower probability function, usually non-additive but having a weaker property: it is a belief function [24]. This requirement is perfectly justified in some situations (see [6]). The general form of lower probabilities has been studied by several authors (see e.g. [30, 31]). Moreover, in many decision problems, in which we have not enough information, decision makers often feel that they are only able to assign an interval value for the probability of events. In other words, they do not know the real probability distribution but there exists a set of probabilities compatible with the available information. Let us call this set of all compatible probabilities \mathcal{P}_1 and let us define $\mu := \inf_{P \in \mathcal{P}_1} P$; then, μ is a capacity (but not necessarily a belief function [29]); μ is called “coherent lower probability”, and it is the natural “lower probability function”. Of course, if P' is a probability measure dominating μ , it is clear that $E_{P'}(f) \geq \int f d\mu$, for any function f , where $\int f d\mu$ represents Choquet integral [3]. Chateauneuf and Jaffray use this fact and that $\mu \leq P, \forall P \in \mathcal{P}_1$ in [2] to obtain an easy method for computing a lower bound of $\inf_{P \in \mathcal{P}_1} E_P(f)$ when μ satisfies some additional conditions (namely μ is 2-monotone). Their method is based on obtaining the set of all probability distributions dominating μ . The same can be done for obtaining an upper bound. In this case, we can find a similar motivation for studying the set of all k -additive capacities dominating a capacity.

The paper is organized as follows: In next section we give the basic concepts about k -additive

capacities and about the set of dominating probabilities. Section 3 is devoted to characterize the vertices for the n -additive case and, in Section 4, we deal with possible generalizations for the k -additive case. In Section 5 we outlined the case of dominated k -additive capacities. We finish with the conclusions and open problems.

2 Basic concepts

We will use the following notation throughout the paper: we suppose a finite universal set with n elements, $N = \{1, \dots, n\}$. Subsets of N are denoted by capital letters A, B , and so on. The set of subsets of N is denoted by $\mathcal{P}(N)$, while the set of subsets whose cardinality is less or equal than k is denoted by $\mathcal{P}^k(N)$.

Definition 1. [21] *A game over N is a mapping $v : \mathcal{P}(N) \rightarrow \mathbb{R}$ (called **characteristic function**) satisfying $v(\emptyset) = 0$.*

If, in addition,

1. *v satisfies $v(A) \leq v(B)$ whenever $A \subseteq B$, the game v is said to be **monotone**;*
2. *v satisfies $v(A \cup B) = v(A) + v(B)$ whenever $A, B \subseteq N$, $A \cap B = \emptyset$, the game is said to be **additive**;*
3. *v satisfies $v(A \cup B) + v(A \cap B) \geq v(A) + v(B)$, for all $A, B \subseteq N$, the game is said to be **convex**.*

From the point of view of Game Theory, for any $A \subseteq N$, the value $v(A)$ represents the minimum asset the coalition of players A will win if the game is played, whatever the remaining players may do, i.e., $v(A)$ is the payoff that coalition A can guarantee for itself. We will denote by $\mathcal{G}(N)$ the set of all games on N .

Definition 2. *A non-additive measure [7] or capacity [3] or fuzzy measure [27] μ over N is a monotone game with $\mu(N) = 1$.*

Consider a monotone game different from the trivial game defined by $v(A) = 0, \forall A \subseteq N$. In this case, we can divide all the values of v by $v(N)$ so that we obtain a new game μ equivalent to v . Then, μ is a capacity and we conclude that any monotone game can be equivalently represented by a capacity. Observe that the set of all capacities on N is a convex polytope, that we will denote $\mathcal{FM}(N)$.

There are other set functions that can be used to equivalently represent a game. We will need in this paper the so-called Möbius transform.

Definition 3. [23, 14] *Let v be a game on N . The **Möbius transform** (or **dividends**) of v is a set function on N defined by*

$$m_v(A) := \sum_{B \subseteq A} (-1)^{|A \setminus B|} v(B), \forall A \subseteq N.$$

The Möbius transform given, the original characteristic function can be recovered through the *Zeta transform* [2]:

$$v(A) = \sum_{B \subseteq A} m_v(B). \quad (1)$$

The value $m(A)$ represents the strength of subset A in any coalition in which it appears.

Let us turn to the concept of k -additivity, originally defined for capacities. In order to define a capacity, $2^n - 2$ values are necessary; the number of coefficients grows exponentially with n , and so does the complexity of the problem. This drawback reduces considerably the practical use of capacities. Then, some subfamilies of capacities have been defined in an attempt to reduce the complexity. Examples of subfamilies include the λ -measures [28], the k -intolerant capacities [16], the k -additive capacities [10], the p -symmetric capacities [20], the decomposable capacities [9], etc. In this paper we will use k -additive capacities.

Definition 4. [10] *A game v is said to be k -order additive or k -additive for short if its Möbius transform vanishes for any $A \subseteq N$ such that $|A| > k$, and there exists at least one subset A of exactly k elements such that $m(A) \neq 0$.*

Additive games are 1-additive games, and so probability measures are 1-additive capacities; thus, k -additive capacities generalize probability measures. More about k -additive capacities can be found, e.g., in [12]. We will denote by $\mathcal{FM}^k(N)$ (resp. $\mathcal{G}^k(N)$) the set of all k' -additive capacities (resp. games) with $k' \leq k$. Observe that $\mathcal{FM}^k(N)$ is a subpolytope of $\mathcal{FM}(N)$. Notice also that $\mathcal{FM}^n(N) = \mathcal{FM}(N)$.

Let us now introduce the concept of k -additive monotone core.

Definition 5. *Let v, v^* be games in $\mathcal{G}(N)$. We say that v^* **dominates** v , and we denote it $v^* \geq_d v$, if and only if*

$$v^*(A) \geq v(A), \forall A \subset N, v^*(N) = v(N).$$

Definition 6. *Let v be a game. We say that a vector $x = (x_1, \dots, x_n) \in \mathbb{R}^n$ is a **pre-imputation** for v if it satisfies*

$$\sum_{i=1}^n x_i = v(N).$$

Remark 1. *For any $x \in \mathbb{R}^n$, it is convenient to use the notation $x(A) := \sum_{i \in A} x_i$, for all $A \subseteq N$, with the convention $x(\emptyset) = 0$. Thus, x identifies with an additive game.*

The value x_i is the asset player i receives when sharing $v(N)$. Suppose that the pre-imputation satisfies $x(A) \geq v(A)$, for all $A \subseteq N$. Then, no subcoalition of players has interest to form, since they will receive more by the sharing (x_1, \dots, x_n) . In other words, any such (x_1, \dots, x_n) is a possible satisfactory pre-imputation for all players.

Definition 7. [25] *Let v be a game. The **core** of v , denoted by $\mathcal{C}(v)$, is defined by*

$$\mathcal{C}(v) := \{x \in \mathbb{R}^n \mid x(A) \geq v(A), \forall A \subseteq N, x(N) = v(N)\}.$$

Since by Remark 1 any $x \in \mathbb{R}^n$ induces an additive game, the core can be equivalently defined as the set of additive games dominating v ; if we are dealing with capacities, the core consists in the set of probabilities dominating the capacity. When nonempty, the core is usually taken as the solution of the game. If the core is not empty, it is a convex polytope and its vertices are known when the game is convex:

Definition 8. A maximal chain in 2^N is a sequence of subsets $A_0 := \emptyset, A_1, \dots, A_{n-1}, A_n := N$ such that $A_i \subset A_{i+1}$, $i = 0, \dots, n-1$. The set of maximal chains of 2^N is denoted by $\mathcal{M}(2^N)$.

To each maximal chain $C := \{\emptyset, A_1, \dots, A_n = N\}$ in $\mathcal{M}(2^N)$ corresponds a unique permutation σ on N such that $A_1 = \sigma(1)$, $A_2 \setminus A_1 = \sigma(2)$, \dots , $A_n \setminus A_{n-1} = \sigma(n)$. The set of all permutations over N is denoted by $\mathfrak{S}(N)$. Let v be a game. Each permutation σ (or maximal chain C) induces an additive game ϕ^σ (or ϕ^C) on N defined by:

$$\phi^\sigma(\{\sigma(i)\}) := v(\{\sigma(1), \dots, \sigma(i)\}) - v(\{\sigma(1), \dots, \sigma(i-1)\})$$

or

$$\phi^C(\{\sigma(i)\}) := v(A_i) - v(A_{i-1}), \quad \forall i \in N,$$

with the above notation.

Theorem 1. The following propositions are equivalent.

1. v is a convex game.
2. All additive games ϕ^σ , $\sigma \in \mathfrak{S}(N)$, belong to the core of v .
3. $\mathcal{C}(v) = \text{co}(\{\phi^\sigma\}_{\sigma \in \mathfrak{S}(N)})$.
4. $\text{ext}(\mathcal{C}(v)) = \{\phi^\sigma\}_{\sigma \in \mathfrak{S}(N)}$,

where $\text{co}(\cdot)$ and $\text{ext}(\cdot)$ denote respectively the convex hull of some set, and the extreme points of some convex set.

(i) \Rightarrow (ii) and (i) \Rightarrow (iv) are due to Shapley [25], while (ii) \Rightarrow (i) was proved by Ichiishi [15].

Suppose the core of the game is empty. Since from Remark 1 the core is the set of 1-additive dominating games, it is natural to look for 2-additive games dominating v ; if this set is empty too, then look for 3-additive games dominating v and so on. This leads us to the following definition.

Definition 9. [19] A game v on N is called k -balanced if there exists a k -additive game dominating it and no game in $\mathcal{G}^{k-1}(N)$ dominates v .

Definition 10. [19] Given a game v , we define the k -additive core of v , denoted by $\mathcal{C}^k(v)$, as the set of all k -additive games dominating v , i.e.,

$$\mathcal{C}^k(v) := \{v^* \in \mathcal{G}^k(N) \mid v^* \geq_d v\}.$$

In [19], the following has been proved:

Proposition 1. For any $k \geq 2$ and any game $v \in \mathcal{G}(N)$, $\mathcal{C}^k(v) \neq \emptyset$.

Consequently, for the general case, only the core and the 2-additive core make sense. Moreover, it has been shown in [13] that the 2-additive core is an unbounded convex polyhedron.

On the other hand, when dealing with capacities, the following notion makes sense:

Definition 11. A capacity μ on N is **k -balanced monotone** if there exists a k -additive capacity dominating it and no capacity in $\mathcal{FM}^{k-1}(N)$ dominates μ .

Definition 12. Given a k -balanced monotone capacity μ , we define the **k -additive monotone core of μ** , denoted by $\mathcal{MC}^k(\mu)$, as the set of all k -additive capacities dominating μ .

Notice that if μ is a balanced capacity, $\mathcal{C}^1(\mu) = \mathcal{MC}^1(\mu) = \mathcal{C}(\mu)$.

If nonempty, it is easy to see that $\mathcal{MC}^k(\mu)$ is a polytope. In next sections we will study its vertices.

3 The set $\mathcal{MC}^n(\mu)$.

In this section we provide an algorithm for obtaining all the vertices of $\mathcal{MC}^n(\mu)$ for a given capacity μ . We consider the following procedure.

- Let \prec be a linear order on $\mathcal{P}(N) \setminus \{N, \emptyset\}$. This order allows us to rank the different subsets of N ,

$$A_1 \prec A_2 \prec \dots \prec A_{2^n-2}.$$

- Next, define a partition $\mathcal{P} = \{\mathcal{U}, \mathcal{L}\}$ on $\mathcal{P}(N) \setminus \{N, \emptyset\}$, where \mathcal{U} or \mathcal{L} could be empty. The aim of the procedure is to define a capacity $\mu_{\prec, \mathcal{P}}$ dominating μ .

- **Initializing step:** Let us define

$$\bar{\mu}^0(A_i) := 1, \underline{\mu}^0(A_i) := \mu(A_i), \forall A_i.$$

- **Iterating step:** For $i = 1$ until $i = 2^n - 2$, do:

- If $A_i \in \mathcal{U}$, then assign

$$\mu_{\prec, \mathcal{P}}(A_i) := \bar{\mu}^{i-1}(A_i).$$

Redefine:

For $\underline{\mu}^i$, we put

$$\underline{\mu}^i(B) = \begin{cases} \max\{\bar{\mu}^{i-1}(A_i), \underline{\mu}^{i-1}(B)\} & \text{if } B \supseteq A_i \\ \underline{\mu}^{i-1}(B) & \text{otherwise} \end{cases}$$

For $\bar{\mu}^i$, we put

$$\bar{\mu}^i(B) = \bar{\mu}^{i-1}(B), \forall B \subset N.$$

– If $A_i \in \mathcal{L}$, then assign

$$\mu_{\prec, \mathcal{P}}(A_i) = \underline{\mu}^{i-1}(A_i).$$

Redefine:

For $\bar{\mu}^i$, we put

$$\bar{\mu}^i(B) = \begin{cases} \min\{\underline{\mu}^{i-1}(A_i), \bar{\mu}^{i-1}(B)\} & \text{if } B \subseteq A_i \\ \bar{\mu}^{i-1}(B) & \text{otherwise} \end{cases}$$

For $\underline{\mu}^i$, we put

$$\underline{\mu}^i(B) = \underline{\mu}^{i-1}(B), \forall B \subset N.$$

The idea of the procedure is the following: In step i , the values for $\mu_{\prec, \mathcal{P}}(A_1), \dots, \mu_{\prec, \mathcal{P}}(A_{i-1})$ are fixed. Consider A_i ; if $A_i \in \mathcal{U}$, we assign to $\mu_{\prec, \mathcal{P}}(A_i)$ the largest possible value keeping dominance and monotonicity, which is $\bar{\mu}^i(A_i)$. Similarly, if $A_i \in \mathcal{L}$, we assign to $\mu_{\prec, \mathcal{P}}(A_i)$ the smallest possible value keeping dominance and monotonicity, which is $\underline{\mu}^i(A_i)$. Once the value of $\mu_{\prec, \mathcal{P}}(A_i)$ is fixed, we need to actualize the lower and upper bounds for $A_j, j > i$. These lower and upper bounds are stored in $\underline{\mu}^i$ and $\bar{\mu}^i$, respectively. For example, for $A_i \in \mathcal{L}$ and for any B such that $B \subset A_i$ whose value has not been fixed yet, in order to keep monotonicity, the value of the capacity on B cannot exceed $\underline{\mu}^{i-1}(A_i)$, whence the maximum value that the capacity on B can attain is given by

$$\min\{\underline{\mu}^{i-1}(A_i), \bar{\mu}^{i-1}(B)\}.$$

A similar argument applies if $A_i \in \mathcal{U}$.

Note that μ itself is a vertex of $\mathcal{MC}^n(\mu)$, appearing when $\mathcal{L} = \mathcal{P}(N) \setminus \{N, \emptyset\}$ and $\mathcal{U} = \emptyset$, no matter which order \prec is considered. Similarly, the measure attaining value 1 for every subset except the empty set is another vertex of $\mathcal{MC}^n(\mu)$, appearing when $\mathcal{U} = \mathcal{P}(N) \setminus \{N, \emptyset\}$ and $\mathcal{L} = \emptyset$, no matter which order \prec is considered. The capacity μ is the least element of this set. Similarly, the measure attaining value 1 for every subset except the empty set is the greatest element of $\mathcal{MC}^n(\mu)$.

The figure explains the performance of the algorithm for the special case of $|N| = 2$. In this case, $\mathcal{P}(N) \setminus \{N, \emptyset\} = \{\{1\}, \{2\}\}$ and we have an antichain. Then, \prec has no relevance in the algorithm. The set $\mathcal{MC}^n(\mu)$ is clearly the yellow square in the figure below. We can see that $\mathcal{MC}^2(\mu)$ has four vertices, corresponding to the four possibilities for \mathcal{U} and \mathcal{L} .

In next results we will prove that the function $\mu_{\prec, \mathcal{P}}$ obtained through this procedure is a vertex of $\mathcal{MC}^n(\mu)$ and that any vertex can be obtained through a suitable choice of \prec and \mathcal{P} .

Proposition 2. $\mu_{\prec, \mathcal{P}} \in \mathcal{MC}^n(\mu)$.

The proof of this result is based on the following lemmas, that provide us with additional properties of the sequences $\{\bar{\mu}^i(B)\}_{i=0}^{2^n-2}$ and $\{\underline{\mu}^i(B)\}_{i=0}^{2^n-2}$.

Lemma 1. For any $B \subset N$, the sequence $\{\underline{\mu}^i(B)\}_{i=1}^{2^n-2}$ is nondecreasing. Similarly, the sequence $\{\bar{\mu}^i(B)\}_{i=0}^{2^n-2}$ is nonincreasing.

Proof: The result is obvious from the definition of $\bar{\mu}^i$ and $\underline{\mu}^i$ in each iteration. ■

Lemma 2. $\underline{\mu}^i, \bar{\mu}^i \in \mathcal{FM}(N), \forall i = 0, \dots, 2^n - 2$.

Proof: We show the result for $\bar{\mu}^i$; the same can be done for $\underline{\mu}^i$.

Clearly, in each iteration $\bar{\mu}^i(B) \in [0, 1], \forall B \subset N$. Thus, it suffices to show the monotonicity. We will prove the result by induction on i .

Consider $A, B \subset N$ such that $A \subset B$. In the initializing step, $\bar{\mu}^0(A) = \bar{\mu}^0(B) = 1$ and the result holds. Therefore, assume the result is true for iterations $0, 1, \dots, i - 1$.

- If $A_i \in \mathcal{U}$, then $\bar{\mu}^i = \bar{\mu}^{i-1}$ and the result holds by the induction hypothesis.
- If $A_i \in \mathcal{L}$, we have three different possibilities.
 - If $A \subset B \subseteq A_i$, then

$$\bar{\mu}^i(A) = \min\{\underline{\mu}^{i-1}(A_i), \bar{\mu}^{i-1}(A)\} \leq \min\{\underline{\mu}^{i-1}(A_i), \bar{\mu}^{i-1}(B)\} = \bar{\mu}^i(B),$$

as $\bar{\mu}^{i-1}(A) \leq \bar{\mu}^{i-1}(B)$ by the induction hypothesis. Thus, the result holds.

- If $A \not\subseteq A_i$, then $\bar{\mu}^i(A) = \bar{\mu}^{i-1}(A)$ and $\bar{\mu}^i(B) = \bar{\mu}^{i-1}(B)$, and the result holds by the induction hypothesis.
- If $A \subseteq A_i, B \not\subseteq A_i$, then

$$\bar{\mu}^i(A) = \min\{\underline{\mu}^{i-1}(A_i), \bar{\mu}^{i-1}(A)\} \leq \bar{\mu}^{i-1}(A) \leq \bar{\mu}^{i-1}(B),$$

applying again the induction hypothesis. On the other hand, $\bar{\mu}^i(B) = \bar{\mu}^{i-1}(B)$, so that the result holds. ■

Lemma 3. $\bar{\mu}^i \geq_d \underline{\mu}^i, \forall i = 0, \dots, 2^n - 2$.

Proof: We will prove the result by induction on i . For the initializing step, the result trivially holds. Take $B \subset N$ and assume then that the result is true for iterations $0, 1, \dots, i - 1$.

Suppose $A_i \in \mathcal{U}$, the other case being symmetric.

- If $A_i \not\subseteq B$, then $\bar{\mu}^i(B) = \bar{\mu}^{i-1}(B)$ and $\underline{\mu}^i(B) = \underline{\mu}^{i-1}(B)$, whence the result holds by induction.

- Otherwise, $\bar{\mu}^i(B) = \bar{\mu}^{i-1}(B)$ and

$$\underline{\mu}^i(B) = \max\{\bar{\mu}^{i-1}(A_i), \underline{\mu}^{i-1}(B)\}.$$

Note that $\bar{\mu}^{i-1}(B) \geq \bar{\mu}^{i-1}(A_i)$ as $\bar{\mu}^{i-1} \in \mathcal{FM}(N)$ (Lemma 2). On the other hand, $\bar{\mu}^{i-1}(B) \geq \underline{\mu}^{i-1}(B)$ by induction, whence $\bar{\mu}^i(B) \geq \underline{\mu}^i(B)$ in the i -th iteration and the result holds. \blacksquare

Proof of the proposition: First, let us see that $\mu_{\prec, \mathcal{P}} \in \mathcal{FM}(N)$.

Clearly, $\mu_{\prec, \mathcal{P}}(B) \in [0, 1]$, $\forall B \subset N$. Thus, it suffices to check the monotonicity. Take $A, B \subset N$ such that $A \subset B$. Suppose $A \prec B$; a similar proof can be derived when $B \prec A$. Thus, $A = A_i$ and $B = A_j$ for some i, j such that $j > i$.

- If $A \in \mathcal{L}$, then $\mu_{\prec, \mathcal{P}}(A) = \underline{\mu}^{i-1}(A)$. By Lemma 2,

$$\underline{\mu}^{i-1}(A) \leq \underline{\mu}^{i-1}(B), \quad \bar{\mu}^{i-1}(A) \leq \bar{\mu}^{i-1}(B).$$

Now,

- If $B \in \mathcal{L}$, then $\mu_{\prec, \mathcal{P}}(B) = \underline{\mu}^{j-1}(B)$ and result holds because, by Lemma 1, we know that $\{\underline{\mu}^i(B)\}_{i=1}^{2^n-2}$ is a nondecreasing sequence.
- Otherwise, $B \in \mathcal{U}$, whence

$$\mu_{\prec, \mathcal{P}}(B) = \bar{\mu}^{j-1}(B) \geq \underline{\mu}^{j-1}(B)$$

by Lemma 3 and the result holds again applying Lemma 1.

- If $A \in \mathcal{U}$, then $\mu_{\prec, \mathcal{P}}(A) = \bar{\mu}^{i-1}(A)$. By construction,

$$\underline{\mu}^i(B) = \max\{\bar{\mu}^{i-1}(A), \underline{\mu}^{i-1}(B)\} \geq \mu_{\prec, \mathcal{P}}(A).$$

- If $B \in \mathcal{L}$, then $\mu_{\prec, \mathcal{P}}(B) = \underline{\mu}^{j-1}(B)$ and result holds because, by Lemma 1, we know that $\{\underline{\mu}^i(B)\}_{i=1}^{2^n-2}$ is a nondecreasing sequence.
- Otherwise, $B \in \mathcal{U}$, whence

$$\mu_{\prec, \mathcal{P}}(B) = \bar{\mu}^{j-1}(B) \geq \underline{\mu}^{j-1}(B)$$

by Lemma 3 and the result holds, again applying Lemma 1.

Therefore, the result holds.

Let us now prove that $\mu_{\prec, \mathcal{P}} \geq_d \mu$.

In the initializing step, we have $\underline{\mu}^0(A) = \mu(A)$, $\forall A \subset N$. Besides, by Lemma 2, we know that $\{\underline{\mu}^i(A)\}_{i=1}^{2^n-2}$ is a nondecreasing sequence. Moreover, by Lemma 3, $\underline{\mu}^i(A) \leq \bar{\mu}^i(A)$, $\forall i$. Thus, as $\mu_{\prec, \mathcal{P}}(A)$ is either $\underline{\mu}^i(A)$ or $\bar{\mu}^i(A)$ for some i , we always obtain $\mu_{\prec, \mathcal{P}}(A) \geq \mu(A)$. \blacksquare

Indeed, it can be easily seen that $\underline{\mu}^i \leq \mu_{\prec, \mathcal{P}} \leq \bar{\mu}^i$, $\forall i$. Moreover, the following holds.

Proposition 3. $\mu_{\prec, \mathcal{P}}$ is a vertex of $\mathcal{MC}^n(\mu)$.

Proof: Consider $\mu_{\prec, \mathcal{P}}$ and let us suppose that there exist $\mu_1, \mu_2 \in \mathcal{MC}^n(\mu)$ such that $\mu_{\prec, \mathcal{P}} = \alpha\mu_1 + (1 - \alpha)\mu_2$, $\alpha \in (0, 1)$. We will prove by induction on i that $\mu_{\prec, \mathcal{P}}(A_i) = \mu_1(A_i) = \mu_2(A_i)$.

Consider A_1 . If $A_1 \in \mathcal{U}$, then $\mu_{\prec, \mathcal{P}}(A_1) = 1$, whence $\mu_1(A_1) = \mu_2(A_1) = 1$. Otherwise, $A_1 \in \mathcal{L}$ and $\mu_{\prec, \mathcal{P}}(A_1) = \mu(A_1)$, whence $\mu_1(A_1) = \mu_2(A_1) = \mu(A_1)$ because they dominate μ .

Now, suppose the result holds until $i - 1$. Assume $A_i \in \mathcal{L}$, the other case being symmetric.

- If $\mu_{\prec, \mathcal{P}}(A_i) = \mu(A_i)$, then $\mu_1(A_i) = \mu_2(A_i) = \mu(A_i)$ because they dominate μ .
- Otherwise, by construction of $\underline{\mu}^{i-1}$, there exists $j < i$ such that $A_j \subset A_i$ and $A_j \in \mathcal{U}$ satisfying

$$\bar{\mu}^{j-1}(A_j) = \underline{\mu}^{j-1}(A_i) = \underline{\mu}^{i-1}(A_i).$$

Consequently, $\mu_{\prec, \mathcal{P}}(A_j) = \bar{\mu}^{j-1}(A_j) = \underline{\mu}^{i-1}(A_i) = \mu_{\prec, \mathcal{P}}(A_i)$. On the other hand, $\mu_1(A_j) = \mu_2(A_j) = \mu_{\prec, \mathcal{P}}(A_j)$ by induction. As $\mu_1 \in \mathcal{FM}(N)$, it follows by monotonicity that

$$\mu_1(A_i) \geq \mu_1(A_j) = \mu_{\prec, \mathcal{P}}(A_j) = \mu_{\prec, \mathcal{P}}(A_i).$$

Similarly, $\mu_2(A_i) \geq \mu_{\prec, \mathcal{P}}(A_i)$ whence $\mu_1(A_i) = \mu_2(A_i) = \mu_{\prec, \mathcal{P}}(A_i)$. ■

Finally, it can be seen that all the vertices can be derived from this procedure.

Proposition 4. If μ^* is a vertex of $\mathcal{MC}^n(\mu)$, then there exists an order \prec and a partition \mathcal{P} of $\mathcal{P}(N) \setminus \{N, \emptyset\}$ such that $\mu^* = \mu_{\prec, \mathcal{P}}$.

Proof: Take μ^* a vertex of $\mathcal{MC}^n(\mu)$. We will show that we can build an order \prec and a partition \mathcal{P} such that $\mu^* = \mu_{\prec, \mathcal{P}}$.

Let us define

$$\mathcal{A}_1 := \{A \in \mathcal{P}(N) \setminus \{N, \emptyset\} \mid \mu^*(A) = \mu(A) \text{ or } \mu^*(A) = 1\}.$$

Take any linear order \prec on \mathcal{A}_1 . If $A \in \mathcal{A}_1$ and $\mu^*(A) = 1$, then $A \in \mathcal{U}$. Otherwise, $A \in \mathcal{L}$.

If $\mathcal{A}_1 = \mathcal{P}(N) \setminus \{N, \emptyset\}$, let us prove by induction that $\mu^* = \mu_{\prec, \mathcal{P}}$.

Take A_1 . If $A_1 \in \mathcal{U}$, then $\mu_{\prec, \mathcal{P}}(A_1) = \bar{\mu}^0(A_1) = 1$, whence $\mu_{\prec, \mathcal{P}}(A_1) = \mu^*(A_1)$ and the result holds. Otherwise, $A_1 \in \mathcal{L}$ and $\mu_{\prec, \mathcal{P}}(A_1) = \underline{\mu}^0(A_1) = \mu(A_1)$, whence $\mu_{\prec, \mathcal{P}}(A_1) = \mu^*(A_1)$ and the result holds.

Take $i > 1$ and assume the result holds until $i - 1$. Suppose $A_i \in \mathcal{U}$, the case $A_i \in \mathcal{L}$ being symmetric. Let us show that $\mu_{\prec, \mathcal{P}}(A_i) = 1 = \mu^*(A_i)$. As $A_i \in \mathcal{U}$, it follows that $\mu_{\prec, \mathcal{P}}(A_i) = \bar{\mu}^{i-1}(A_i)$. We have two different cases:

- If there exists no $j < i$ such that $A_j \in \mathcal{L}$ and $A_j \supset A_i$, then by the construction of the procedure, it is $\bar{\mu}^{i-1}(A_i) = \bar{\mu}^0(A_i) = 1$ and the result holds.

- Otherwise,

$$\bar{\mu}^{i-1}(A_i) = \min\{\mu_{\prec, \mathcal{P}}(A_j) \mid j < i, A_j \in \mathcal{L}, A_j \supset A_i\}.$$

By the induction hypothesis, $\mu_{\prec, \mathcal{P}}(A_j) = \mu^*(A_j), \forall j < i$, whence

$$\bar{\mu}^{i-1}(A_i) = \min\{\mu^*(A_j) \mid j < i, A_j \in \mathcal{L}, A_j \supset A_i\}.$$

By construction of \mathcal{L} , we have $\mu^*(A_j) < 1, \forall A_j \in \mathcal{L}$. Thus, $\bar{\mu}^{i-1}(A_i) < 1$. On the other hand, $A_i \in \mathcal{U}$, whence $\mu^*(A_i) = 1$ by construction of \mathcal{U} . But then, there exists $A_j \supset A_i$ such that $\mu^*(A_i) > \mu^*(A_j)$, whence μ^* is not monotone, a contradiction. Therefore, this second case is not possible.

We conclude that if $\mathcal{A}_1 = \mathcal{P}(N) \setminus \{N, \emptyset\}$, then $\mu^* = \mu_{\prec, \mathcal{P}}$ and we are done.

Otherwise, define

$$\mathcal{A}_2 := \{A \in (\mathcal{P}(N) \setminus \{N, \emptyset\}) \setminus \mathcal{A}_1 \mid \mu^*(A) = \mu^*(B), B \in \mathcal{A}_1, B \subset A \text{ or } B \supset A\}.$$

Range the subsets in \mathcal{A}_2 in any way after the subsets in \mathcal{A}_1 . If $A \in \mathcal{A}_2$ and $\mu^*(A) = \mu^*(B)$ for $B \in \mathcal{A}_1$ and $B \supset A$, then $A \in \mathcal{U}$. Otherwise, $A \in \mathcal{L}$.

As in the previous case, if $\mathcal{A}_2 = (\mathcal{P}(N) \setminus \{N, \emptyset\}) \setminus \mathcal{A}_1$, then it can be checked that $\mu^* = \mu_{\prec, \mathcal{P}}$ and we are done.

Otherwise, we can reiterate the process defining \mathcal{A}_3 and so on. If at some step the whole $\mathcal{P}(N) \setminus \{N, \emptyset\}$ is recovered, then $\mu^* = \mu_{\prec, \mathcal{P}}$ and the result holds. Let us see that this is always the case.

Suppose there exists an i such that $\mathcal{A}_i = \emptyset$ and $\mathcal{A}_1 \cup \dots \cup \mathcal{A}_{i-1} \neq \mathcal{P}(N) \setminus \{N, \emptyset\}$. Then, we can define

$$\mu_1(B) = \begin{cases} \mu^*(B) & \text{if } B \in \mathcal{A}_1 \cup \dots \cup \mathcal{A}_{i-1} \\ \mu^*(B) + \epsilon & \text{otherwise} \end{cases} \quad \mu_2(B) = \begin{cases} \mu^*(B) & \text{if } B \in \mathcal{A}_1 \cup \dots \cup \mathcal{A}_{i-1} \\ \mu^*(B) - \epsilon & \text{otherwise} \end{cases}$$

As we are dealing with a finite number of subsets, it is possible to take an $\epsilon > 0$ such that $\mu_1, \mu_2 \in \mathcal{FM}(N)$. Moreover, ϵ can be chosen so that $\mu_1, \mu_2 \in \mathcal{MC}^n(\mu)$. But $\mu^* = \frac{1}{2}\mu_1 + \frac{1}{2}\mu_2$, whence μ^* is not a vertex of $\mathcal{MC}^n(\mu)$, a contradiction.

This finishes the proof. ■

Note that these results allow us to derive an upper bound for the number of vertices of $\mathcal{MC}^n(\mu)$.

Proposition 5. *The number of vertices of $\mathcal{MC}^n(\mu)$ is bounded by $(2^n - 2)!2^{2^n - 2}$.*

Proof: The number of possible orders \prec is $(2^n - 2)!$. On the other hand, for a fixed order, there are $2^{2^n - 2}$ possible partitions \mathcal{P} . ■

Observe that the number of vertices can be far below this bound as it could be the case that some possibilities lead to the same capacity. For example, we have already seen that μ can be obtained by taking $\mathcal{L} = \mathcal{P}(N) \setminus \{N, \emptyset\}$, no matter the order \prec . Even more, if $\mu(A) = 1, \forall A \neq \emptyset$, then $\mathcal{MC}^n(\mu) = \{\mu\}$ and consequently, all possibilities lead to the same vertex μ .

Remark 2. An interesting case arises when μ is an extreme point of $\mathcal{FM}(N)$. In this case, μ is a $\{0, 1\}$ -valued measure [22], and it can be trivially seen that the procedure developed in this section leads to $\{0, 1\}$ -valued measures, i.e. vertices of $\mathcal{FM}(N)$. This means that the set of vertices of $\mathcal{MC}^n(\mu)$ is the set of vertices of $\mathcal{FM}(N)$ dominating μ . As a vertex of the polytope of fuzzy measures is characterized by the family of minimal subsets [18], the smallest subsets such that $\mu(A) = 1$, if $\{C_1, \dots, C_k\}$ are the minimal subsets of μ , then

$$\mathcal{MC}^n(\mu) = \{\mu^* \in \mathcal{FM}(N) : \mu^*(A) = 1 \forall A \mid \exists C_i \subseteq A\}.$$

On the other hand, it has been proved in [4] that $\mathcal{FM}(N)$ is an order polytope [26] for the poset $\mathcal{P}(N) \setminus \{\emptyset, N\}$ and the partial order defined by the containing condition.

Remark that $\mathcal{MC}^n(\mu)$ fixes the values of some subsets of N ; then, we can partitionate $\mathcal{P}(N) \setminus \{\emptyset, N\}$ in terms of subsets of N with the same value; this partition π on the poset $\mathcal{P}(N) \setminus \{\emptyset, N\}$ is given by the classes $[\mathcal{C}] \cup \{[A] := \{A\}, C_i \not\subseteq A, i = 1, \dots, k\}$ where

$$[\mathcal{C}] = \{A \in \mathcal{P}(N) \setminus \{\emptyset, N\} \mid \exists C_i \subseteq A\}.$$

This partition is trivially compatible with the containing partial order and it is also a connected partition of the poset $\mathcal{P}(N) \setminus \{\emptyset, N\}$. Thus, the set $\mathcal{MC}^n(\mu)$ can be seen as a quotient of the order polytope $\mathcal{FM}(N)$ [4], and we can apply the results of [26] to conclude that $\mathcal{MC}^n(\mu)$ is indeed a face of the polytope $\mathcal{FM}(N)$.

4 The case of $\mathcal{MC}^k(\mu)$

In this section we treat the general k -additive case, $1 \leq k < n$. The basic idea is to translate the results of the previous section to this case. In order to do this, we will need to solve two new problems:

- For a fixed value of $\mu^*(A)$, the possible lower and upper bounds of $\mu^*(B)$, $B \neq A$ are not trivial, as it happened for the n -additive case. Moreover, if we are dealing with $\mathcal{MC}^k(\mu)$, it could be the case that $\mu \notin \mathcal{FM}^k(N)$. Thus, μ cannot be taken as the least element for $\mathcal{MC}^k(\mu)$, and it could be the case that $\mathcal{MC}^k(\mu)$ have not a least element, so that $\underline{\mu}^0$ could not be defined. Similarly, the measure attaining value 1 for every subset is n -additive and thus, it is no longer in $\mathcal{MC}^k(\mu)$, whence it could be the case that $\mathcal{MC}^k(\mu)$ have not a greatest element, so that $\overline{\mu}^0$ could not be defined.
- Contrary to $\mathcal{FM}^n(N)$, the structure of the polytope $\mathcal{FM}^k(N)$ is not known for $k \geq 3$. Indeed, it has been proved in [18] that there are vertices of $\mathcal{FM}^k(N)$, $k \geq 3$ that are not $\{0, 1\}$ -valued measures; moreover, to our knowledge, no description of these vertices has been achieved. However, it could be the case that some of these vertices are in $\mathcal{MC}^k(\mu)$. How can they be characterized?

In order to partially solve the first problem, we will study in this section the particular case in which $\mu \in \mathcal{FM}^k(N)$. Then, $\mathcal{MC}^k(\mu) \neq \emptyset$ and has a least element (μ itself). Moreover, μ can be

used as the lower bound in the initial step. Notice that in the n -additive case these properties trivially hold.

Note also that for a capacity in $\mathcal{FM}^k(N)$, if we consider its Möbius transform, we only need to define the values for subsets in $\mathcal{P}^k(N) \setminus \{\emptyset\}$. As the Möbius transform is an equivalent representation of the capacity by Eq. (1), we conclude that we only need to consider the values of the capacity on subsets whose cardinality lies between 1 and k in order to completely define a k -additive capacity.

Taking these facts in mind, the procedure goes as follows:

- IN:

- Let us consider a total order on $\mathcal{P}^k(N) \setminus \{\emptyset\}$. This total order allows us to rank the subsets: $A_1 \prec A_2 \prec \dots \prec A_r$, where $r = \sum_{i=1}^k \binom{n}{i}$.
- Next, take a partition $\mathcal{P} = \{\mathcal{U}, \mathcal{L}\}$ on $\mathcal{P}^k(N) \setminus \{\emptyset\}$, where \mathcal{U} or \mathcal{L} could be empty.

- OUT:

- **Initializing step:** Let us define $\mu^0 := \mu$
- **Iterating step:** For $i = 1$ until $i = r$ do:
 - * If $A_i \in \mathcal{L}$, then $\mu^i = \mu^{i-1}$.
 - * Otherwise $A_i \in \mathcal{U}$.

1. Let us consider the subset given by

$$\mathcal{B} := \{\mu^* \in \mathcal{FM}^k(N) \mid \mu^* \geq_d \mu^{i-1}, \mu^*(A_j) = \mu^{i-1}(A_j), j = 1, \dots, i-1\}.$$

2. Look for $\bar{s} := \max_{\mu^* \in \mathcal{B}} \{\mu^*(A_i)\}$.
3. Define

$$\mathcal{A}_0 := \{\mu^* \in \mathcal{B} \mid \mu^*(A_i) = \bar{s}\}.$$

- (a) If $\mathcal{A}_0 = \{\mu^*\}$, then define $\mu^i := \mu^*$.
- (b) Otherwise:

- Initialize $j = 1$.
- Repeat until $|\mathcal{A}_j| = 1$.
- Look for $\underline{s}_{i+j} := \min_{\mu^* \in \mathcal{A}_{j-1}} \{\mu^*(A_{i+j})\}$.
- Define

$$\mathcal{A}_j := \{\mu^* \in \mathcal{A}_{j-1} \mid \mu^*(A_{i+j}) = \underline{s}_{i+j}\}.$$

- $j = j + 1$.
- If $\mathcal{A}_j = \{\mu^*\}$, define $\mu^i := \mu^*$.

Let us explain the procedure. The whole process spins around the capacities μ^i . By construction $\mu^i \in \mathcal{FM}^k(N)$, $\forall i \geq 1$. Observe also that μ^i can be built because $\mu^0 = \mu \in \mathcal{FM}^k(N)$. Moreover, $\mu^i \leq_d \mu^{i+1}$, $\forall i$. Indeed, μ^i represents the lower bounds for A_j , $j > i$ when the values on A_1, \dots, A_i are fixed. Thus, following the same spirit as in the previous section, we want

that, at step i , the values for A_1, \dots, A_{i-1} are already fixed. This is done through the property $\mu^i(A_j) = \mu^{i+1}(A_j)$, $\forall j < i$ that appears in the definition of \mathcal{B} .

Suppose we are in step i , so that we are dealing with A_i . If $A_i \in \mathcal{U}$, we look for a capacity μ^i whose value on A_i is the largest possible value provided that $\mu^i \geq_d \mu^{i-1}$ and that the values $\mu^i(A_1), \dots, \mu^i(A_{i-1})$ are already fixed; the possible candidates are capacities in \mathcal{B} . As $\mathcal{FM}^k(N)$ is a polytope, so is \mathcal{B} . Thus, for A_i , it follows that the capacity on A_i can vary in an interval whose lower bound is $\mu^{i-1}(A_i)$, and whose upper bound is \bar{s} . For the n -additive case, once this value is found, the procedure modifies the upper and lower bounds for the values on $A_k, k > i$. In the present case, the problem is not that simple because it might be the case that no greatest element exist. Thus, we only look for the lower bounds.

We proceed as follows: Once \bar{s} is obtained, it could be the case that several capacities reach this value, i.e. it could happen that \mathcal{A}_0 is not a singleton. Our capacity μ^i should be chosen in \mathcal{A}_0 and ideally, it should be the least element in this set. However, it could be the case that such least element do not exist; in other words, we can find several capacities that are not dominated for any other capacity in \mathcal{A}_0 , i.e. these capacities are not comparable as vectors. In order to solve this problem, we take as μ^i the capacity in \mathcal{A}_0 that takes the minimum value on A_{i+1}, A_{i+2}, \dots ; this is done through $\mathcal{A}_1, \mathcal{A}_2, \dots$. This finishes in a finite number of steps because necessarily \mathcal{A}_{r-i} is a singleton.

On the other hand, if $A_i \in \mathcal{L}$, then we look for the smallest k -additive capacity dominating μ^{i-1} , that is μ^{i-1} itself because $\mu^{i-1} \in \mathcal{FM}^k(N)$. And we define $\mu^i := \mu^{i-1}$ for next iteration.

Therefore this algorithm coincides with the algorithm of the previous section for the n -additive case.

Consider μ^r , the capacity obtained in the last iteration. We will prove that it is a vertex of $\mathcal{MC}^k(\mu)$.

Lemma 4. *The measure μ^r is an extreme point of $\mathcal{MC}^k(\mu)$.*

Proof: Consider μ^r and let us suppose that there exist $\mu_1, \mu_2 \in \mathcal{MC}^k(\mu)$ such that $\mu^r = \alpha\mu_1 + (1 - \alpha)\mu_2$, $\alpha \in (0, 1)$. We will prove by induction on iteration i that $\mu^r(A_i) = \mu_1(A_i) = \mu_2(A_i)$.

Consider A_1 . If $A_1 \in \mathcal{U}$, then $\mu^r(A_1)$ attains the maximum possible value for a measure in $\mathcal{MC}^k(\mu)$, whence $\mu_1(A_1) = \mu_2(A_1) = \mu^r(A_1)$.

Otherwise, $A_1 \in \mathcal{L}$ and $\mu^r = \mu(A_1)$, whence $\mu_1(A_1) = \mu_2(A_1) = \mu(A_1)$ because both of them belong to $\mathcal{MC}^k(\mu)$.

Now, take $i > 1$ and assume the result holds until $i - 1$.

Suppose $A_i \in \mathcal{L}$. By construction of μ^r , it is $\mu^r(A_i) = \mu^{i-1}(A_i)$. On the other hand, by construction of μ^{i-1} , this capacity is such that it assigns to $\mu^{i-1}(A_i)$ the smallest possible value keeping dominance on μ and satisfying $\mu^{i-1}(A_j) = \mu^r(A_j) \forall j < i$. But this implies that $\mu_1(A_i) = \mu_2(A_i) = \mu^r(A_i)$ by induction.

Similarly, if $A_i \in \mathcal{U}$, by construction μ^r assigns to A_i the greatest possible value while keeping dominance on μ and satisfying $\mu^{i-1}(A_j) = \mu^r(A_j) \forall j < i$. But this implies that $\mu_1(A_i) = \mu_2(A_i) = \mu^r(A_i)$ by induction. \blacksquare

However, this method does not obtain all the vertices of $\mathcal{MC}^k(\mu)$, as next example shows:

Example 1. *Consider $|N| = 4$ and the measure $u_{\{1,4\}}$ given by $u_{\{1,4\}}(A) = 1$ if $\{1,4\} \subseteq A$ and $u_{\{1,4\}}(A) = 0$ otherwise. Consider the measure μ^* given by*

Subset	1	2	3	4	1,2	1,3	1,4	2,3	2,4	3,4	1,2,3	1,2,4	1,3,4	2,3,4
μ^*	0	0	0	0	0.5	0.5	1	0.5	0	0	0.5	1	1	1

It has been proved in [18] that μ^* is an extreme point of $\mathcal{FM}^3(N)$. On the other hand, $\mu^* \geq u_{\{1,4\}}$, whence μ^* is an extreme point of $\mathcal{MC}^3(u_{\{1,4\}})$. Let us check that μ^* cannot be obtained through the previous algorithm, no matter the order considered.

Assume $A_1 \in \mathcal{U}$.

- If $A_1 = \{2\}$ then we can consider the capacity μ' whose Möbius transform is given by

$$m'(2) = 1, m'(1,4) = 1, m'(1,2,4) = -1, m'(A) = 0 \text{ otherwise.}$$

Thus, we have obtained a dominating capacity in $\mathcal{FM}^3(N)$ such that $\mu'(2) = 1$, whence μ^* could not be derived. The same can be done if $A_1 = \{3\}$.

- If $A_1 = \{1\}$ then we can consider the capacity whose Möbius transform is given by

$$m'(1) = 1, m'(A) = 0 \text{ otherwise.}$$

Thus, we have obtained a dominating capacity in $\mathcal{FM}^3(N)$ such that $\mu'(1) = 1$, whence μ^* could not be derived. The same can be done if $A_1 = \{4\}$.

- If $A_1 = \{1,3\}$ then we can consider the capacity whose Möbius transform is given by

$$m'(1,3) = 1, m'(1,4) = 1, m'(1,3,4) = -1, m'(A) = 0 \text{ otherwise.}$$

Thus, we have obtained a dominating capacity in $\mathcal{FM}^3(N)$ such that $\mu'(1,3) = 1$, whence μ^* could not be derived. The same can be done for any pair different from $\{1,4\}$ and $\{2,3\}$.

- Suppose $A_1 = \{2,3\}$ and consider the capacity whose Möbius transform is given by

$$m'(2,3) = 1, m'(1,4) = 1, m'(1,2) = 1, m'(1,2,3) = -1, m'(1,2,4) = -1, m'(A) = 0 \text{ otherwise.}$$

In this case, we obtain a 3-additive measure dominating $u_{\{1,4\}}$ and thus, it is possible to obtain $\mu_1(2,3) = 1$. Therefore, μ^* cannot be derived in this case.

- If $A_1 = \{1,2,3\}$, we can consider the capacity whose Möbius transform is given by

$$m'(1,2) = 1, m'(1,4) = 1, m'(1,2,4) = -1, m'(A) = 0 \text{ otherwise.}$$

Thus, we have obtained a dominating capacity in $\mathcal{FM}^3(N)$ such that $\mu'(1,2,3) = 1$, whence μ^* could not be derived.

- For the other possibilities, we have $u_{\{1,4\}}(A_1) = 1$, whence the value is fixed.

Consequently, it is not possible to obtain μ^* if $A_1 \in \mathcal{U}$. Thus, assume $A_1 \in \mathcal{L}$. This fixes $\mu^1(A_1) = u_{\{1,4\}}(A_1)$.

- If $A_1 \in \{\{1,2\}, \{1,3\}, \{2,3\}, \{1,2,3\}\}$, then $\mu^1(A_1) = 0$, whence μ^* cannot be recovered.

- For other possibilities, we fix a value either 0 or 1.

But then, we can repeat the process for A_2 with the same results. Thus, μ^* cannot be obtained through the procedure.

5 On the polytope of dominated k -additive capacities

In the previous sections we have considered a profit game, the value $\mu(A)$ representing the payoff that the coalition A can guarantee, i.e. we are dealing with winning quantities. A dual problem arises if $\mu(A)$ denotes losing quantities. In this case, we look for dominated capacities instead of dominating capacities and the concepts of core, k -additive core, and so on can be translated to this case accordingly.

Let μ be a capacity and suppose that we are interested in the set of k -additive capacities that are **dominated** by μ . As before, it can be seen that this set is a polytope, so that it suffices to study its vertices.

In this case, we can apply the results of the previous sections. For this, it suffices to note that

$$\mu \leq_d \mu^* \Leftrightarrow \overline{\mu^*} \leq_d \overline{\mu},$$

where $\overline{\mu}$ denotes the dual capacity of μ , defined by

$$\overline{\mu}(A) = 1 - \mu(A^c), \forall A \subseteq X.$$

Observe that $\overline{\overline{\mu}} = \mu$ and that the dual of a k -additive capacity is a k -additive capacity [17].

Moreover, if μ' is a vertex of the polytope of the dominated k -additive capacities, then $\overline{\mu'}$ is a vertex of dominating k -additive capacities of $\overline{\mu}$. For if there exist $\mu_1, \mu_2 \in \mathcal{MC}^k(\overline{\mu})$ such that $\overline{\mu'} = \alpha\mu_1 + (1-\alpha)\mu_2$, $\alpha \in (0, 1)$, then $\mu' = \alpha\overline{\mu_1} + (1-\alpha)\overline{\mu_2}$. As $\overline{\mu_1}$ and $\overline{\mu_2}$ are k -additive capacities dominated by μ , we conclude that μ' is not a vertex of the set of dominated k -additive capacities, a contradiction.

Consequently, for a given capacity μ , we can consider $\overline{\mu}$, apply the results of the previous sections and then apply again duality. For example, the procedure for obtaining the set of vertices of the polytope of dominated n -additive capacities can be written as:

- Let \prec be a linear order on $\mathcal{P}(N) \setminus \{N, \emptyset\}$. This order allows us to rank the different subsets of N ,

$$A_1 \prec A_2 \prec \dots \prec A_{2^n-2}.$$

- Next, define a partition $\mathcal{P} = \{\mathcal{U}, \mathcal{L}\}$ on $\mathcal{P}(N) \setminus \{N, \emptyset\}$, where \mathcal{U} or \mathcal{L} could be empty. The aim of the procedure is to define a capacity $\mu_{\prec, \mathcal{P}}$ dominated by μ .

- **Initializing step:** Let us define

$$\underline{\mu}^0(A_i) := 0, \overline{\mu}^0(A_i) := \mu(A_i), \forall A_i.$$

- **Iterating step:** For $i = 1$ until $i = 2^n - 2$, do:

- If $A_i \in \mathcal{U}$, then assign

$$\mu_{\prec, \mathcal{P}}(A_i) := \overline{\mu}^{i-1}(A_i).$$

Redefine:

For $\underline{\mu}^i$, we put

$$\underline{\mu}^i(B) = \begin{cases} \max\{\overline{\mu}^{i-1}(A_i), \underline{\mu}^{i-1}(B)\} & \text{if } B \supseteq A_i \\ \underline{\mu}^{i-1}(B) & \text{otherwise} \end{cases}$$

For $\overline{\mu}^i$, we put

$$\overline{\mu}^i(B) = \overline{\mu}^{i-1}(B), \forall B \subset N.$$

– If $A_i \in \mathcal{L}$, then assign

$$\mu_{\prec, \mathcal{P}}(A_i) = \underline{\mu}^{i-1}(A_i).$$

Redefine:

For $\overline{\mu}^i$, we put

$$\overline{\mu}^i(B) = \begin{cases} \min\{\underline{\mu}^{i-1}(A_i), \overline{\mu}^{i-1}(B)\} & \text{if } B \subseteq A_i \\ \overline{\mu}^{i-1}(B) & \text{otherwise} \end{cases}$$

For $\underline{\mu}^i$, we put

$$\underline{\mu}^i(B) = \underline{\mu}^{i-1}(B), \forall B \subset N.$$

6 Conclusions

In this paper, we have characterized the vertices of the n -additive core; these results generalize the Shapley-Ichiishi theorem of probabilities for the general case. Observe that in this case no conditions on μ are required, while in the Shapley-Ichiishi theorem convexity is needed.

Next, we have treated the possible extensions for the k -additive case. Finally, the dual case for dominated k -additive capacities is treated.

It should be noted that in Example 1 we have considered a capacity $u_{\{1,4\}}$ of $\mathcal{FM}^3(N)$ and a vertex of $\mathcal{FM}^3(N)$ dominating $u_{\{1,4\}}$. Notice that this vertex is not $\{0, 1\}$ -valued. In [18], it has been proved that these vertices might appear for the polytope $\mathcal{FM}^k(N)$ when $3 \leq k \leq n - 1$. On the other hand, the vertices of $\mathcal{FM}^1(N)$, $\mathcal{FM}^2(N)$ and $\mathcal{FM}^n(N)$ (the general case) are $\{0, 1\}$ -valued. Thus, it arises the question of whether this algorithm holds for $k = 1, 2$.

If $k = 1$ and μ is a probability, then the set $\mathcal{MC}^1(\mu) = \mathcal{C}(\mu) = \{\mu\}$. In this case the algorithm holds and the problem is trivial. The 2-additive case remains an open problem and deeper research is needed.

Related to Example 1, we have the problem of whether the procedure developed in Section 4 obtains all the vertices of $\mathcal{MC}^k(\mu)$ that are not vertices of $\mathcal{FM}^k(N)$. If this holds, then the vertices of $\mathcal{MC}^k(\mu)$ could be completed using the procedure developed in [5]. However, verifying this hypothesis seems to be a difficult problem and more research is needed.

In order to determine the vertices of $\mathcal{MC}^k(\mu)$, we could apply a modified version of the procedure developed in [5], but the complexity should be investigated in order to study its practical applicability.

Another important problem arising in the k -additive case is the number of vertices of the k -additive core. For the general n -additive case, the set of vertices of $\mathcal{FM}(N)$ coincides with the

n -th Dedekind number; simulations carried out for the k -additive case [5] seem to show that the number of vertices of $\mathcal{FM}^k(N)$ is even greater, due to vertices that are not $\{0, 1\}$ -valued. This problem could make unfeasible to store all the vertices of the k -additive monotone core in some cases.

Acknowledgements

This research has been supported in part by grant numbers MTM2007-61193, MTM2009-10072 and BSCH-UCM910707.

We also thank a referee for pointing out the special structure of $\mathcal{MC}^n(\mu)$ when μ is a vertex of $\mathcal{FM}(N)$.
